

# **ROOF SLOPE**

Design Guide

SELECTING THE OPTIMUM ROOFING PROFILE FOR APPLICATIONS WHERE ROOF SLOPE IS A KEY CONSIDERATION. INCORPORATES DETAILED REGIONAL RAINFALL INTENSITIES.

#### IMPORTANT NOTICE AND DISCLAIMER

The information contained within this brochure is for general use and information only. Before application in a particular situation, Stramit recommends that you obtain appropriate independent qualified expert advice confirming the suitability of product(s) and information in question for the application proposed. While Stramit accepts its legal obligations, be aware however that to the extent permitted by law, Stramit disclaims all liability (including liability for negligence) for all loss and damage resulting from the use of the information provided in this brochure.

#### **ROOF SLOPE FACTORS**

The major factors when considering roof slopes are

- Economy
- Safety
- Drainage
- Services
- Durability
- Aesthetics
- Wind resistance

This guide focuses particular attention on drainage and gives comprehensive information on the drainage characteristics of Stramit's range of roofing profiles. This, along with rainfall data for major locations, will enable easy selection of the best product for each application.

#### **ECONOMY**

Roof slope can have a significant effect on the cost of a building. The extent of this effect is dependent on building size and proportions. Generally the longer the roof slope and the lower the building height the greater the cost reduction from minimising roof slope. These savings are in the wall structure and wall cladding. It should be realised however that increasing the roof slope sufficiently could reduce wind pressures and lower the roof structure cost.

### DRAINAGE

#### **DESIGN BASIS**

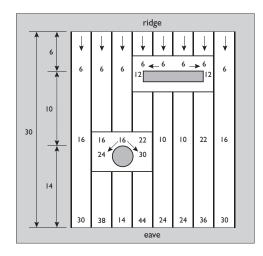

All roof slope/drainage capacities in this publication are based on rainfall intensity of a 100 year ARI (Average Recurrence Interval) of 5 minutes duration and AS1562.1. The effective flow areas of roofing profiles are conservative. They are based on water being limited to the depth fully below each profile anti-capillary feature, and further reduced by a freeboard allowance. Tests at University of Technology, Sydney on several Stramit profiles have confirmed the adequacy of the data.

#### **ROOF RUN LENGTH**

The roof run length is the combined length of roofing run contributing to water flow in any one sheeting pan (or trough) at the lowest edge. If roof penetrations or spreaders are present it is likely that the maximum roof run length will exceed the distance from the ridge to the eaves.

(Note - if practical place roof penetrations towards the top of a roof slope where water flow is less significant.)

Water flow is complex. However a simplified method of estimating water flow is generally satisfactory. The illustration shows a typical roof arrangement where two penetrations influence the roof run length in various sheeting pans. Although the nominal roof length is 30m, the Maximum Roof Run Length is 44m in this case. This increase will be lower if water is re-directed back into the original pans below the penetrations.

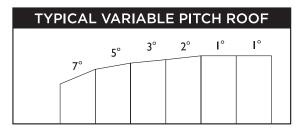

#### **CURVED ROOFS**

Spring-curved convex roofs can provide an excellent solution to roof drainage, particularly on large roofs. A convex curve approximates the increasing volume of water along the roof run and therefore can lead to efficient structures. Information on spring-curving of Stramit profiles can be found in the publication Spring Curving Guide.

#### VARIABLE PITCH ROOFS

On very large roofs drainage can lead to increases in roof slope and consequent increases in structure cost. A practical method to reduce the structure in these cases is to vary the pitch down the roof. Taking advantage of occasional expansion joints, each segment of roof sheeting can be at the optimised slope. For each roof segment the maximum roof run length is only considered from the lowest point of that segment to the ridge. The effects of any roof penetrations must be accounted for.

## DURABILITY

Durability is considered from the perspective of minimum fall and the benefit of additional fall.

#### MINIMUM SLOPE

It is essential that the minimum fall of roof is maintained to ensure that water drains away. This minimum must be maintained over the entire roof, and throughout the life of the building. Water ponding on the roof will gather dirt and airborne particles. This compounds the problem by retaining moisture after most water has dried, and also soaking up condensation and dew. The ensuing prolonged exposure of a section of the roof to a damp 'chemical soup' will reduce life expectancy.

The minimum slopes set by Stramit for its profiles are based on two factors. These are sheeting stiffness (which resists permanent deflection) and the ability of a profile to be turned up or down at the sheet ends to prevent incursion of wind blown rain.

#### THE BENEFIT OF ADDITIONAL SLOPE

Further durability benefits can be gained from increasing slope. The major benefit comes from increased cleanliness. Increasing slope increases water velocity and assists gravity and wind in removing debris. A minimum slope of around 5° is considered necessary to achieve these benefits.

#### WIND RESISTANCE

Many factors influence wind pressure on a building, and on the roof in particular. These include site factors such as location, topography and exposure, as well as building geometry factors such as height, plan ratio and permeability. The slope of the roof is another factor. The influence of slope on wind pressures is interdependent on the building geometry factors. There is however a trend worth considering in building design.

As wind uplift pressure is often the limiting criterion in roof sheet sizing and spacing, it can be worth minimising. This can only be achieved by increasing the slope to 10° or more. At 20° the pressure can actually halve. Further increases to 45° have little effect, and beyond this pressures generally increase. Use AS/NZS1170.2 when considering changes to roof slope to reduce wind pressure.

#### **SAFETY**

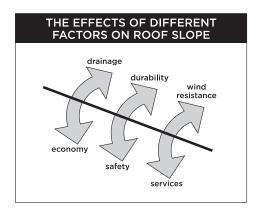

Metal roof sheeting has a relatively smooth surface and, particularly in combination with oil from manufacture or surface water, can be slippery. Increasing the slope increases this risk. It is difficult to define a safe slope: however, roofs with a slope of more than around 25° require the use of ladders or walkwavs.

#### **SERVICES**

Where services are to be installed on the roof it is generally more convenient to minimise the roof slope. This will make installation and maintenance easier, improve safety and may reduce the visual impact.

#### **AESTHETICS**

For many buildings the roof forms a major visual component. Whether it be minimising slope to hide necessary rooftop services, or increasing the slope for overall visual balance, this guide will assist in selecting the correct product for the desired slope.

#### **HOW TO USE**

- 1. Calculate the maximum roof run length.
- 2. Establish the rainfall intensity for the location of the building. These can be read from the table for many Australian locations, or find the rainfall intensity from the Bureau of Meteorology web site using Latitude and Longitude.
- 3. Using the Roof Slope table for the next highest rainfall intensity, select a roofing profile and slope to match the maximum roof run length.
- 4. Check that the selected product is available for the building location using the Regional Product Availability chart.

#### **REGIONAL RAINFALL INTENSITY**

Values of rainfall intensity in the table have been derived from the National Construction Code Volume Two and the Bureau of Meteorology website. Specific data for any location can be obtained from the Bureau of Meteorology website based on the Latitude and Longitude. It should however be emphasised that the extent and longevity of records in Australia are limited and any such data therefore carries with it a degree of uncertainty.
